ESE 524 - Homework 3

Database Problems and Solutions Assigned date: 02/19/19 Due Date: 03/05/19

Total Points: 100 + 20 Extra Credit

1) Maximum Likelihood Estimation

Consider samples $\mathbf{x} = [x[0], ..., x[N-1]]^T$ from a model:

$$x[n] = \theta^{1/2} s[n] r[n] + w[n]$$

where $\mathbf{s} = [s[0], ..., s[N-1]]^T$ is a known signal, $\mathbf{r} = [r[0], ..., r[N-1]]^T$ and $\mathbf{w} = [w[0], ..., w[N-1]]^T$ are i.i.d. $\mathcal{N}(0,1)$ random variables, and $\theta \geq 0$ is an unknown parameter.

- (a) (10 pts) Suppose $s[n] \in \{-1, 1\}$ is a sequence of +1's and -1's, what is the maximum likelihood estimate (MLE) of θ ?
- (b) (10 pts) Compute the bias as well as variance of your estimate from a), and compare the latter with the Cramer-Rao bound (CRB). [*Hint*: You do not need to calculate the CRB of θ].

2) Linear Models

In linear models, we have $x = H\theta + w$, where x is our observation, θ is the parameter vector to be estimated, and $w \sim N(0, C)$ is colored Gaussian noise with covariance matrix C. Assume that C is positive definite.

(a) (5 pts) Compute the CRB of θ .

Hint: recall that Fisher information $I(\theta) = \text{cov}_{p(x;\theta)} \left[\frac{\partial}{\partial \theta} \log p(x;\theta) \right]$. Further, $\frac{\partial x^T S x}{\partial x} = 2Sx$ if S is symmetric, $\frac{\partial x^T a}{\partial x} = a$, and $\frac{\partial a^T x}{\partial x} = a$.

- (b) (5 pts) Show that the estimator $\hat{\theta} = (\mathbf{H}^T \mathbf{C}^{-1} \mathbf{H})^{-1} \mathbf{H}^T \mathbf{C}^{-1} \mathbf{x}$ is unbiased and efficient, i.e., the MVUE, by comparing the covariance matrix and CRB.
- (c) (10 pts) In order to estimate θ better, we use two different linear systems to get two independent observations x_1 and x_2 :

$$\boldsymbol{x}_1 = \boldsymbol{H}_1 \boldsymbol{\theta} + \boldsymbol{w}_1$$

$$\boldsymbol{x}_2 = \boldsymbol{H}_2 \boldsymbol{\theta} + \boldsymbol{w}_2$$

where $w_1 \sim N(\mathbf{0}, C_1)$ and $w_2 \sim N(\mathbf{0}, C_2)$. Write the MVUE for $\boldsymbol{\theta}$ by using the above two observations. Write the MVUE for $\boldsymbol{\theta}$ if only one observation, for example x_1 , is available. Compare the covariance matrices of these two MVUEs (Recall that for positive semidefinite matrices \boldsymbol{A} and \boldsymbol{B} , we write $\boldsymbol{A} \geq \boldsymbol{B}$, if $\boldsymbol{A} - \boldsymbol{B}$ is positive semidefinite and you can assume that $\boldsymbol{H}_1^T \boldsymbol{C}_1^{-1} \boldsymbol{H}_1$ and $\boldsymbol{H}_2^T \boldsymbol{C}_2^{-1} \boldsymbol{H}_2$ are invertible.)

Hint: $(A + B)^{-1} = A^{-1} - A^{-1}(B^{-1} + A^{-1})^{-1}A^{-1}$ if A and B are invertible.

3) Trace of a Matrix

- (a) (10 pts) If $\mathbf{A} \in \mathbb{R}^{m \times n}$, then show that $\|\mathbf{P}\mathbf{A}\mathbf{Q}\| = \|\mathbf{A}\|$, where $\|\cdot\|$ is the Frobenius norm, $\mathbf{P} \in \mathbb{R}^{m \times m}$ and $\mathbf{Q} \in \mathbb{R}^{n \times n}$ are orthogonal matrices.
- (b) (10 pts) Show that expectation and trace operators commute, i.e., if $\mathbf{X} \in \mathbb{R}^{n \times n}$ is a random matrix, then

$$\mathbb{E}[\mathrm{Tr}(\mathbf{X})] = \mathrm{Tr}[\mathbb{E}(\mathbf{X})]$$

4) Maximum Likelihood Estimation

Let X_1, \ldots, X_n be independently identically distributed random variables with probability density function

$$f(x; \sigma, \lambda) = \frac{\sigma^{1/\lambda}}{\lambda} \exp\left[-(1 + \frac{1}{\lambda})\log(x)\right] \mathbb{I}(x \ge \sigma),\tag{1}$$

where $x \ge \sigma$, $\sigma > 0$, and $\lambda > 0$. The indicator function $\mathbb{I}(x \ge \sigma) = 1$ if $x \ge \sigma$ and 0 otherwise. Find the maximum likelihood estimator (MLE) of (σ, λ) denoted as $(\hat{\sigma}, \hat{\lambda})$ with the following steps

- (a) (10 pts) Show that $\hat{\sigma} = X_{(1)} = \min\{X_1, \dots, X_n\}$ is the MLE of σ regardless of the value of $\lambda > 0$.
- (b) (10 pts) Find the MLE of $\hat{\lambda}$ if $\sigma = \hat{\sigma}$ (that is assume σ is known)

5) Maximum Likelihood Estimation for US Household Income - MATLAB Problem

(a) (5 pts) Given a parameter vector $\theta = [\alpha, c, k]$, the Burr Distribution has density function:

$$p(x[n];\theta) = \frac{\frac{kc}{\alpha} \left(\frac{x[n]}{a}\right)^{c-1}}{\left(1 + \left(\frac{x[n]}{a}\right)^{c}\right)^{k+1}} \,\forall \, \alpha, c, k, x[n] > 0.$$

Find the gradient of the log likelihood for N samples.

- (b) (5 pts) Download "income.mat" from Canvas. Use Gradient Descent to find the MLE estimates for α , c, and k based on the data in the income file.
- (c) (5 pts) Use the mle and fmincon commands in MATLAB to find the parameter estimates, and compare them to the estimates from part b).
- (d) (5 pts) Plot a histogram of the income data, as well as the Burr distribution you fitted in either b) or c). [Hint: The yyaxis command in MATLAB can be used to set multiple axes on the same plot.]
- 6) (20 pts) Extra Credit: Come up with an example and solution illustrating one or more concepts from class so far. This example should be something you believe would be good to present in class to help other students understand a concept from the lectures. MATLAB (or other software) simulations are encouraged. Problems can be inspired by or explore applications from literature, but should not just copy the results of a paper.
